Technical Take Home

This will be discussed as part of the interview process.

> This is cloud agnostic, so please use whatever IAC tools and cloud provider you're most familiar with. (It can even be self hosted if that is your preference)
>
> There is a pre-built binary that you can assume is installed to make the recordings. We aren't expecting you to build or develop the recording software itself.
>
> The aim here is to design a resilient architecture for recording audio.

Design the infrastructure for a system that continuously records audio data from radio URLs that writes the output audio to a data bucket.

Requirements:

1. It must run 24/7. We ideally want to record as much audio as possible.
2. It must output to a data bucket, as another system needs to be able to access the audio in order to process it.
3. It should be easy to scale up and down with the number of radio stations (URLs) actively being recorded. As an example, it might need to be able to quickly go from recording 20 radio stations to 100 with minimal or no effort.
4. Include monitoring that highlights gaps in the recorded audio as well as any other monitoring you think would be useful.

Please provide written documentation on the solution. Feel free to provide any other files you think would be of use. This can be sent in whatever format you find easiest, as long as we can read the solution.
